1. Welcome — How to Use This Guide

Hi, I'm Emma.

If you're reading this, chances are you've been staring at a stubborn wart for longer than you'd like to admit. Maybe you've tried a few things already. Maybe it faded for a week and then came right back,

a little bigger and a little more annoying. I want you to know something before we go any further: you're not doing anything wrong, and you are absolutely not alone.

I made this guide because I've been there. I spent months frustrated, embarrassed, and quietly googling at midnight, wondering why nothing seemed to stick. What I eventually learned changed everything — not because I found some miracle, but because I finally understood *why* warts behave the way they do, and what actually makes a difference. That's what I want to hand you here: not hype, just honest, useful information from someone who gets it.

What you'll learn in these pages:

- What a wart actually is, and the one thing about them most people never get told (it's the reason they keep coming back).
- Why so many common approaches treat only the surface — and why that matters more than you'd think.
- A simple, gentle daily protocol you can actually stick to, using natural tools that work *with* your skin instead of against it.
- How to care for the skin around the wart so the rest of you stays comfortable and healthy.
- The patience-and-consistency mindset that, honestly, matters as much as anything you apply.
- And just as importantly — the warning signs that mean it's time to skip the home approach and see a doctor.

How to use this guide: Read it once, start to finish — it's short on purpose. Then keep it somewhere handy and come back to the sections you need. The protocol in the middle is the heart of it; the surrounding chapters are there to help you understand what you're doing and why, so you can make smart choices for *your* skin.

A gentle promise: I'm not here to sell you a fantasy. Skin takes time. Warts can be persistent little things, but with the right understanding and a steady, consistent routine, they are very beatable. Thousands of regular people work through them every day, quietly and patiently — and so can you.

Take a breath. You've already done the hardest part, which is deciding to do something about it. Let's walk through this together.

— Emma

2. What a Wart Actually Is

Before we talk about getting rid of a wart, it helps to understand exactly what one is. If you've ever poked at a wart and wondered, "What *is* this thing, really?" — you're in good company. Most of us go

years without anyone explaining it plainly. So let's fix that.

A wart is a small, harmless growth on the skin caused by a very common virus called HPV (human papillomavirus). There are many different types of HPV, and the ones that cause the warts on your hands, fingers, knees, and feet are completely ordinary — not the kind people sometimes worry about in other contexts. These everyday strains do one simple thing: they get into the top layers of your skin and tell those skin cells to grow faster and thicker than usual. That overgrowth is the bump you see.

Here's the part most people never hear. The visible bump on the surface isn't the whole story. The virus lives down in the deeper layers of that top skin, and the wart is essentially being **fed from below** — many people picture it as having a "root." That's why a wart can feel firmly anchored rather than sitting loosely on top, and it's a big reason warts can be so stubborn. If something only takes off the surface but leaves that deeper part behind, the wart often quietly rebuilds itself. (We'll come back to this idea later, because it changes how you think about getting rid of one.)

Why warts look and feel the way they do:

- They're usually rough, firm, and raised, with a slightly grainy or cauliflower-like surface.
- You might notice tiny black dots in the center — those are just small, clotted blood vessels, not "seeds" or "roots" you can pull out.
- On the soles of your feet (plantar warts), they often grow inward because of the pressure of walking, which can make them feel like a small stone in your shoe.

And please hear this clearly: **a wart is not a sign of poor hygiene.** Warts are incredibly common — most people get at least one in their lifetime, and they're especially ordinary in kids and teens. You can pick up the virus from everyday contact: a shared towel, a locker-room floor, a pool deck, or simply touching one wart and then another spot on your own skin. Clean, healthy people get warts all the time. It's just a common virus doing a common thing.

Now that you know what you're actually dealing with, let's look at the different types — because the one on your knuckle behaves very differently from the one on the bottom of your foot.

3. Know Your Wart: The Common Types

Before you do anything about a wart, it helps to know exactly what you're looking at. They don't all behave the same way, and the one on your knuckle is a very different animal from the one on the bottom of your foot. Here's how to tell yours apart.

Common warts (verruca vulgaris). The classic. These show up most on hands, fingers, knuckles, and around the nails. They're raised, rough, and grainy to the touch, with a domed shape and sometimes tiny black dots in the center (those are just clotted blood vessels, not "seeds," despite the

old myth). They're usually the size of a pencil eraser or smaller. Not painful, but easy to catch on things and easy to notice when you're handing someone your phone or shaking a hand.

Plantar warts. These grow on the soles of your feet, and they're the stubborn ones. Because you walk on them all day, they get pushed inward and flattened, often hiding under a thick callus. You may feel like there's a small stone in your shoe, or a tender spot when you press the ball of your foot. Look closely and you might see that callused area interrupting the normal lines of your skin. They love pressure points and are the type people tend to fight the longest, so be patient with these.

Flat warts (verruca plana). Smaller, smoother, and flatter than the others, often skin-colored or slightly pink. They tend to appear in clusters — sometimes dozens at once — on the face, the backs of the hands, the shins, or anywhere people shave. They're easy to mistake for tiny bumps or clogged pores, which is exactly why they get missed.

Filiform warts. The thread-like ones. These have finger-like projections that stick out from the skin, usually around the eyes, nose, lips, or neck. They tend to grow quickly and are hard to ignore because of where they sit on the face.

Periungual warts. These cluster around and under the fingernails and toenails. They're notoriously persistent, partly because the area is tricky to treat thoroughly, and nail-biters are especially prone to them.

Here's the thread that ties all of them together: no matter the type, each one has a root anchored beneath the surface. That's why location and depth matter more than appearance. Identify which type is yours — and how deep it sits — and you'll understand why the next section is the whole game.

One honest note: if a spot bleeds easily, changes color, grows fast, or doesn't look like any of these, don't guess. Have a doctor take a look. Most warts are harmless, but it's always worth ruling out anything that isn't.

4. Why Warts Keep Coming Back

If you've ever treated a wart, watched it shrink and flake away, felt that little wave of relief... and then noticed it creeping back a few weeks later in the exact same spot, I want you to know something first: it wasn't your fault, and you didn't do anything wrong.

This is one of the most common and most frustrating things about warts, and once you understand *why* it happens, everything about how you treat them starts to make more sense.

The part you can see is only the top.

A wart isn't just a rough bump sitting on your skin. Think of it less like a sticker and more like a small weed. The visible bump is the part above the surface, but underneath, the wart has a base, a root, anchored down into the deeper layers of skin where the virus lives and quietly does its work. That root is the engine. As long as it's intact, it can keep rebuilding the bump on top, even after the surface looks completely clear.

That's the "it looked gone, then it came back" mystery solved. The surface healed. The root didn't.

Why surface-only treatments so often disappoint.

A lot of common approaches work by attacking the top, burning it off with acid, or freezing it. They can absolutely remove the visible bump, sometimes dramatically. But here's the catch: those methods act on the surface, which means the root underneath can be left untouched and survive. Skin grows back over it, the bump returns, and you're starting over, sometimes feeling like you're going backwards.

It's a bit like mowing a weed instead of pulling it. The lawn looks tidy for a while, but the root is still down there, waiting.

The mindset shift that changes everything.

Here's the single most useful idea in this whole book: stop aiming at the bump, and start aiming at the root.

When you shift your goal from "make the surface disappear fast" to "reach and address the root over time," your whole approach changes. You become more patient. You stop panicking when there's no dramatic overnight result, because you understand that real progress is happening below the surface, where you can't see it yet.

In the next sections, we'll talk about *how* to actually reach that root, gently and consistently, without scorching the healthy skin around it. That balance — getting deep enough to matter while staying kind to your skin — is the heart of everything that follows.

5. Why the Usual Treatments Let You Down

If you've already battled a wart or two, you've probably tried at least one of these. None of them are scams, and some can genuinely help. But it's worth understanding what each one actually does to your skin — because that explains why so many of us end up right back where we started.

Salicylic acid (gels, liquids, patches). This is the drugstore classic. Salicylic acid is a keratolytic, which is a fancy way of saying it dissolves the hardened top layers of skin a little at a time. Used patiently — and I mean weeks of daily soaking, filing, and reapplying — it can wear a wart down. The catch is that it works from the top down. It chips away at the surface bump, but it isn't built to travel

deeper, where the wart actually anchors itself. Miss a few days (and most of us do), and the surface rebuilds.

Cryotherapy / freezing. Whether it's a doctor's liquid nitrogen or a home freeze-off kit, the idea is to destroy the wart tissue with extreme cold. It can be effective, but it's blunt. Freezing burns the surface and a bit beneath, often leaving a blister, soreness for days, and sometimes a pale mark or scar once it heals. It frequently takes several rounds. And because it's hard to reach everything below the surface, warts commonly come back near the same spot.

Duct tape. Yes, really — there's a folk method of covering a wart with tape to irritate it and nudge your immune system to respond. It's cheap and harmless, and a few people swear by it. Honestly, the evidence is mixed at best, and it's slow. Think of it as a low-cost experiment, not a plan.

OTC "freeze-off" kits. These bring the freezing approach home. Convenient, but you're working without a doctor's precision, so it's easy to over-treat healthy skin around the wart or under-treat the wart itself.

See the pattern? Acid and freezing are surface-focused. They burn or wear away what you can see, while the part that keeps the wart anchored often survives. That's not a knock on these methods — it's just the honest reason recurrence is so common.

The takeaway isn't "everything's useless." It's that **how deep a treatment reaches matters as much as how aggressive it is.** Keep that in mind as we move into the gentler, more thorough approach in the next sections.

A quick note: if a spot is painful, bleeding, changing color, or spreading fast, skip the home experiments and see a doctor — some things that look like warts aren't.

6. How Tea Tree Oil Works

If you've made it this far, you already know the frustrating part: most quick-fix wart treatments work on the *surface*. Acids and freezing essentially burn or blister the top layer of skin. That can knock back the visible bump for a while, but a wart isn't just what you see. It has roots that reach down into the deeper layers of skin. If those roots are left untouched, the wart often quietly comes back, sometimes in the very same spot. That's the part nobody warns you about, and it's why so many people feel stuck in a cycle.

This is where an oil behaves differently from a surface treatment, and it comes down to one simple property: oil sinks in.

It penetrates instead of burns. Your skin's outer barrier is naturally oil-friendly. A lightweight oil isn't blocked the way water-based products often are. Instead of sitting on top and scorching the surface, it

absorbs *down* into the skin, where it can actually reach the root of the problem rather than just the tip of it. Tea tree oil is a small, light molecule, which is exactly why it travels well and doesn't just pool on the surface.

It's gentle on the healthy skin around it. This is the part I love. Acids and freezing don't know the difference between a wart and the perfectly good skin surrounding it, which is how people end up with stinging, raw patches, and sometimes a mark left behind. A properly diluted oil works without that harsh "burn everything" approach. Used the way I'll walk you through, it's far kinder to the skin you *want* to keep, and that means no scarring from the method itself.

It's patient, and that's a feature. Reaching the root isn't a one-time blast. It's a daily, consistent thing — more tending-a-garden than wielding-a-blowtorch. Slower? A little. But "slow and deep" tends to feel a whole lot better than "fast and harsh," especially on hands, feet, or anywhere sensitive.

A quick honest note on what I use: my go-to is **Kalmely Tea Tree Oil**, simply because it's clean, properly concentrated, and easy to apply precisely, which matters a lot for the routine in the next section. Any pure, well-sourced tea tree oil follows the same principle, so the *method* is what counts most.

One reminder: tea tree oil is for the skin only, never swallowed, and always do a small patch test on nearby skin first to make sure it agrees with you. In the next section, I'll show you exactly how to apply it, step by step.

7. The Wart-Free Protocol, Step by Step

Here's the whole routine on one page. It's simple on purpose — the magic isn't in any single step, it's in doing the simple thing consistently. Read it once, then keep it somewhere you'll see it (the bathroom mirror is my favorite spot).

Step 1: Clean and dry the area.

Wash the wart and the skin around it with warm water and a little soap, then pat it completely dry. A wart you're treating should never be left damp — moisture is exactly what these little guys love. If the surface is thick or rough, you can gently buff the very top with a pumice stone or an emery board you keep *only* for this (never reuse it elsewhere — see the hygiene section). Don't dig, don't force it, don't make it bleed. You're just opening the door, not knocking it down.

Step 2: Apply 1–2 drops directly, twice a day.

Put one or two drops of tea tree oil straight onto the wart — morning and night. A cotton swab gives you control and keeps it off the surrounding skin. This is where the oil does its quiet work: because it's an oil, it soaks *in* rather than sitting on top, reaching down toward the root instead of only scorching

the surface. I use Kalmely tea tree oil because it's clean and undiluted, but the method matters more than the brand. Let it dry for a minute before you cover up or get dressed.

Step 3 (optional): Protect with a small patch.

Covering the spot with a small bandage or hydrocolloid patch after the oil dries does two helpful things — it keeps the oil working a little longer, and it stops you from touching or spreading it. On hands or feet that rub against everything, this is worth it. On a spot that gets good airflow, you can skip it.

Step 4: Consistency over weeks.

This is the real secret, so I'll be honest with you: this works in *weeks*, not days. Most people start noticing the wart looking flatter, darker, or smaller somewhere around the three-to-six-week mark, and stubborn ones can take longer. Normal progress is slow and unglamorous — a gradual shrinking, a change in texture, the edges loosening. Keep going for a week or two *after* it looks gone to discourage it from creeping back.

Don't judge it day to day. Judge it month to month. Mark a calendar, snap a photo each Sunday, and trust the routine.

8. How to Get Results Faster

Tea tree oil works by penetrating down toward the root of the wart, but you can give it a clearer path to travel. None of these accelerators are magic, and none of them replace patience. What they do is remove barriers, so each drop you apply has less dead skin to fight through. Here's how I do it, step by step.

Gently file the dead skin first. Warts build up a thick, hardened layer of dead skin on top, almost like a tiny callus. That layer blocks the oil from reaching deeper. Once or twice a week, after a soak, lightly buff the top of the wart with a disposable emery board or a pumice stone kept *only* for this.

- *Do* use light, gentle passes and stop the moment you feel tenderness.
- *Don't* file until it bleeds, dig, or pick at it. That irritates healthy skin and can spread the virus.
- *Don't* ever reuse that emery board on another part of your body. Toss disposable files; never share them.

Take a short warm soak. Soaking the area in plain warm water for 5 to 10 minutes softens that top layer and makes filing easier and safer. Pat fully dry before you apply your oil. Damp skin dilutes everything.

- *Do* keep it short and use plain warm water.

- *Don't* use scalding water or add harsh chemicals.

Try a hydrocolloid patch overnight. These little patches (the kind made for blemishes) hold moisture against the skin and keep the area covered and protected. After applying your tea tree oil, you can cover it with one. This may help the oil stay put and discourage you from picking.

- *Do* change the patch daily and keep the area clean.
- *Don't* trap dirt under a patch or leave the same one on for days.

Be consistent, and don't stop too early. This is the one that matters most. Twice-a-day application, every single day, beats an intense weekend followed by forgetting for a week. I keep my Kalmely tea tree oil right next to my toothbrush so morning and night happen automatically.

The biggest mistake I see is stopping the moment the wart *looks* better. Remember, the surface can flatten while the root is still there. Keep going for a week or two after it appears gone. Slow and steady really does win here.

And if the area ever becomes painful, red, or starts spreading quickly, pause and check in with your doctor.

9. Mistakes That Make It Worse

Here's the honest truth: most of the time a wart sticks around longer, or comes back, it isn't because the wart was "stubborn." It's because of something we did without realizing. So before we go any further, let's clear the most common slip-ups off your plate.

Don't cut, dig, or "dig it out."

This is the big one. I know the temptation — you just want it gone today. But a wart isn't a callus you can carve off. It has a root that lives deeper than the surface, and slicing the top off only removes the part you can see. The root stays, and now you've also opened a raw wound that can get infected and scar. Surface-only approaches struggle for exactly this reason, which is why working with a penetrating oil like tea tree oil that reaches below the surface tends to be gentler and more patient than going at it with a blade.

Don't pick, peel, or bite it.

Warts spread by contact, including from you, to you. Picking releases what's inside onto your fingertips, and from there it travels — to your other hand, your face, your lip. If you're a nail-biter and there's a wart near a nail, this one matters double. Keep your hands away, and wash after every application.

Don't share towels, washcloths, files, or socks.

Give the affected person their own towel and their own emery board or pumice, and label them. Damp shared items are an easy ride for a wart to reach someone else in the house. Never use the same file on a wart and then on healthy skin or nails.

Don't stop the day it looks gone.

This is the heartbreaker, because it feels like winning. The visible bump can flatten while the root is still alive underneath. Stop too early and it quietly rebuilds. Keep your routine going a little past the point where you think you're done — give it that extra stretch.

Don't over-file into healthy skin.

A light buff helps oil sink in. Filing until it's pink, sore, or bleeding does not speed anything up, it just damages good skin and creates a doorway for spreading. Gentle and consistent beats aggressive every time.

One more: don't stack five products at once. Layering acids, freezing, and oils together usually means irritation, not faster results. Pick a calm, steady approach and give it room to work.

And always, if something looks unusual, bleeds, or changes shape or color, see your doctor.

10. Stop It From Spreading

Here's something most people don't realize until they're dealing with their second or third wart: the same virus that caused the first one (HPV) can travel. It spreads two ways — to other parts of your own skin, and to the people you share a home with. The good news is that a few simple habits make a real difference, and none of them are hard once they become routine.

Don't help it spread to yourself

Warts spread through tiny breaks in the skin, and the virus loves moisture and friction. A few honest habits:

- **Resist picking, scratching, or biting.** This is the number-one way warts multiply. Touching a wart and then touching another spot can plant the virus somewhere new. If you're a picker, keep the wart covered so your fingers have nothing to grab.
- **Keep your own dedicated file or pumice.** If you smooth down a wart before treating it, that file now carries the virus. Use one tool for the wart only, label it, and never let it touch healthy skin or anyone else's. Disinfect it after each use, or use a disposable emery board you throw away.

- **Cover it when it's wet or exposed.** Damp, softened skin (after showers, swimming, or workouts) sheds the virus more easily. A bandage during these times protects both your other skin and the people around you.
- **Wash your hands** after applying any treatment or touching the wart — before you touch your face, eyes, or genitals, where skin is more vulnerable.

Don't pass it to your family

- **Don't share towels, razors, socks, or nail clippers.** Give the affected person their own, and wash towels in hot water.
- **Flip-flops in shared showers.** Bathroom floors, pool decks, locker rooms, and gym showers are classic spots to pick up plantar warts. Sandals are a small, easy shield.
- **Keep the wart dry and covered around shared surfaces** — especially if little ones share the bath.

A gentle note on treatment: this is one reason an oil that soaks in can be kind to a household.

Because Kalmely tea tree oil penetrates the skin rather than burning the surface, there's no raw, weeping wound left exposed to shed virus onto towels and shower floors during treatment — keep the spot covered between applications either way.

Be patient and consistent. Most warts clear with time, and good hygiene keeps you from starting over with a brand-new one. If a wart bleeds easily, changes color, grows fast, or won't respond, see your doctor — that's always the right call.

11. Keeping Them Gone for Good

Here's the part most people skip: once the spot finally clears, you stop paying attention to it. I get it. You've earned a break. But the wart virus (HPV) lives in your skin, and it tends to wake up when your defenses are low. So this last stretch isn't about fear. It's about a few small habits that quietly stack the odds in your favor.

Take care of the skin you have.

Warts love a doorway. Tiny cracks, hangnails, raw cuticles, and dry, split skin all give the virus a way back in. So keep your hands and feet moisturized, especially in winter. Don't bite or pick at hangnails. If you shave over an area that used to have a wart, go gently and use a fresh blade so you're not nicking the skin. Healthy, intact skin is your best barrier, period.

Manage moisture.

Damp, trapped skin is the friendliest environment for warts, particularly on feet. Dry thoroughly between your toes after showers. Rotate your shoes so they fully air out, swap to clean socks daily, and choose breathable materials. At the gym, pool, or locker room, wear flip-flops on wet floors. These are the exact spots where plantar warts tend to start.

Support the immune system that does the real work.

Your body is what keeps HPV in check long-term, so give it the basics it actually needs. Prioritize sleep. Run-down, sleep-deprived people get more breakthroughs. Eat real food with plenty of color, stay hydrated, and move your body regularly. Manage stress in whatever way works for you, because chronic stress wears down immunity over time. None of this is glamorous, but it's the foundation, and it matters more than any single product.

Watch the old spot.

For a few weeks after it clears, keep a quiet eye on where the wart used to be. If you want, dab a little Kalmely tea tree oil on that spot a couple of times a week as gentle upkeep. Because tea tree oil is an oil, it sinks in rather than just sitting on the surface, which makes it an easy maintenance habit.

Act fast if anything returns.

A wart that comes back is far easier to handle when it's small. The moment you notice a familiar rough patch, start your routine again right away. Don't wait and watch it grow.

And one honest reminder: if a spot bleeds, changes color, grows quickly, or just doesn't look right, see a doctor. Staying wart-free is mostly small, steady habits, and you've already done the hard part.

12. Warts in Children — A Gentle Approach

If your child has a wart, take a breath first. Warts in kids are extremely common, almost always harmless, and a normal part of growing up. A young immune system is still learning, so warts show up easily — and, given time, they often fade on their own. Knowing that takes a lot of the pressure off.

Why the harsh methods feel so rough on little ones

Freezing and acid treatments work by deliberately injuring the skin. For an adult that's an annoyance; for a child it can be genuinely scary and painful. Freezing stings sharply and can leave a blister. Acids burn and sometimes irritate the healthy skin around the wart. And here's the frustrating part for parents: because these methods target the surface, the deeper portion under the skin often survives — so after all the tears, the wart can quietly come back. That cycle of pain-and-return is hard on a child's trust, and on yours.

The case for a calm, painless routine

A gentle topical oil routine asks very little of your child: no needles, no burning, no big appointment. Tea tree oil is naturally an oil, so it can seep into the skin rather than scorching the top of it — which is exactly why it's kinder on small, sensitive skin. A drop of Kalmely tea tree oil dabbed on with a cotton swab is usually all it takes. **One important note:** tea tree oil is for skin use only, never to be swallowed, and keep the bottle well out of reach of curious hands. For very young children, or any wart on the face or near the eyes, check with your pediatrician before starting.

Turn it into a bedtime ritual

Children relax into routine. Tie the dab onto something they already do — right after teeth-brushing, just before a story. Let them "help" hold the swab or count to ten. A tiny adhesive bandage over the spot can feel like a reward and keeps the oil where it belongs overnight. Keep your own tone light and matter-of-fact; kids read our worry, so calm is contagious.

Patience and reassurance

This is a slow, steady approach — think weeks, gently, not an overnight fix. Skipping a night is fine; consistency over time matters more than perfection. Remind your child (and yourself) that the wart is leaving on its own schedule, and that nothing about this should hurt.

See your doctor if a wart bleeds, changes color, spreads quickly, becomes painful, or you're simply unsure — when in doubt, a quick check is always the right call.

13. When to See a Doctor

Most common warts are harmless, and home care is a perfectly reasonable place to start. But part of being good to your skin is knowing when it's time to let a professional take a look. There's no shame in it, and asking for help early often saves you time, worry, and discomfort down the road. Here are the signs that tell me it's time to pick up the phone.

See a doctor if you notice any of these:

- **You're not sure it's a wart.** This is the big one. Warts can look like other skin growths, and a few of those need a trained eye. If you have any doubt at all about what you're looking at, get it checked before you treat it. Don't self-diagnose a growth you can't confidently identify.
- **It's changing quickly** in size, shape, or color, especially if it darkens, develops irregular borders, or looks very different from the warts you've had before.
- **It bleeds easily, hurts, or won't stop being tender.** A wart that's painful, oozing, or bleeding without you bumping it deserves professional attention.

- **It's spreading fast** to new areas despite consistent, gentle care, or you're suddenly developing many at once.
- **Warts in sensitive areas.** Anything in the genital area, on the face, or around the eyes, lips, or mouth should be handled by a doctor, not at home. Genital warts in particular are a different situation entirely and need a medical visit.

Some health conditions call for extra caution. If you have diabetes, poor circulation, a weakened immune system, or you take medication that affects your immune system, please skip home treatment and see your doctor first. Your skin heals differently, and what's minor for one person can become complicated for you. The same goes for warts on the soles of your feet if you have diabetes — never treat those yourself.

Also worth a visit: warts that are persistent and stubborn after a long, patient stretch of consistent care, or that are interfering with walking, writing, or daily life.

A doctor has options you don't have at home and, just as importantly, can confirm you're actually dealing with a common wart in the first place. Think of professional help as a partner to your natural routine, not a failure of it. Trust your instincts. If something feels off, you deserve real answers, and a quick appointment is always worth the peace of mind.

14. Myths, Facts & Your Questions Answered

Before we say goodbye, let's clear the air. There's a lot of old folklore floating around about warts, and some of it makes people feel embarrassed or do the wrong thing. Here's the honest version.

Myth 1: "You got it from touching a frog (or a toad)."

Pure storybook stuff. Frogs and toads have nothing to do with it. Warts are caused by a common, everyday virus (HPV) that lives on surfaces and passes through tiny breaks in the skin. The frog had an alibi.

Myth 2: "Warts mean you're dirty or unhygienic."

Not true, and please let this one go. The cleanest people in the world get warts. It's simply a virus that found a doorway — a small cut, a damp gym floor, a shared towel. It says nothing about you.

Myth 3: "You always need to burn or freeze it off."

This is the big one. Freezing and acid work by burning the *surface* of the wart. The trouble is the wart has a root that lives below the surface — so when only the top is destroyed, the root often survives and the wart quietly grows back. That's why so many people freeze the same wart three or four times. The gentler route is an oil that can actually *penetrate* the skin rather than scorch it. That's the whole

idea behind a quality tea tree oil like the Kalmely bottle in your kit — it works *with* your skin instead of against it.

Myth 4: "Cover it up and it'll get worse."

Actually the opposite. Keeping a wart covered (a small patch or tape) limits the moisture and air it loves, protects the area, and lowers the chance of spreading it to your other fingers or to other people.

Myth 5: "If it disappears, it's gone for good — guaranteed."

Because it's a virus, it can occasionally return. That's normal, not failure. Keep the skin healthy and you tilt the odds in your favor.

Quick FAQ

- *How long does it take?* Skin is slow and personal — usually a few weeks of daily consistency. Patience beats picking.
 - *Can I cover it?* Yes, please do.
 - *Will it scar?* Gentle, non-burning approaches are kind to the skin around the wart, which is exactly the point.
 - *What if it comes back?* Restart your routine calmly, and see the doctor checklist if anything looks unusual, painful, or changes shape.

A Closing Note from Emma

You made it to the end — and honestly, that says something about you.

When I was in the thick of this, what I wanted most wasn't a magic fix. It was someone to explain things plainly, treat me like I had some sense, and remind me that I wasn't failing just because my skin needed time. That's what I've tried to be for you in these pages.

So here's what I'll leave you with. Be patient — skin moves at its own pace, not ours. Be consistent — the small, boring, twice-a-day habit is where the real progress lives. And be gentle with yourself, both in how you treat your skin and in how you talk to yourself while you wait. You're not behind. You're not doing it wrong. You're just doing the steady, unglamorous work that actually pays off.

Keep this guide somewhere handy. Come back to the protocol when you need a refresher, the warning-signs list when something feels off, and this page whenever you need a little reassurance. And remember: if anything ever looks unusual, changes, or worries you, a quick visit to the doctor is always the right call — that's not giving up, that's being smart.

You've got this. Truly. I'm rooting for you.

Warmly,

Emma
